1 Preprocessing

In this lab, we will be exploring how to preprocess tweets for sentiment analysis. We will provide a function for preprocessing tweets during this week's assignment, but it is still good to know what is going on under the hood. By the end of this lecture, you will see how to use the [NLTK](#) package to perform a preprocessing pipeline for Twitter datasets.

1.1 Setup

You will be doing sentiment analysis on tweets in the first two weeks of this course. To help with that, we will be using the [Natural Language Toolkit \(NLTK\)](#) package, an open-source Python library for natural language processing. It has modules for collecting, handling, and processing Twitter data, and you will be acquainted with them as we move along the course.

For this exercise, we will use a Twitter dataset that comes with NLTK. This dataset has been manually annotated and serves to establish baselines for models quickly. Let us import them now as well as a few other libraries we will be using.

```
In [1]: import nltk                                # Python library for NLP
        from nltk.corpus import twitter_samples    # sample Twitter dataset from NLTK
        import matplotlib.pyplot as plt           # library for visualization
        import random                              # pseudo-random number generator
```

1.2 About the Twitter dataset

The sample dataset from NLTK is separated into positive and negative tweets. It contains 5000 positive tweets and 5000 negative tweets exactly. The exact match between these classes is not a coincidence. The intention is to have a balanced dataset. That does not reflect the real distributions of positive and negative classes in live Twitter streams. It is just because balanced datasets simplify the design of most computational methods that are required for sentiment analysis. However, it is better to be aware that this balance of classes is artificial.

The dataset is already downloaded in the Coursera workspace. In a local computer however, you can download the data by doing:

```
In [ ]: # downloads sample twitter dataset. uncomment the line below if running on a local machine
        # nltk.download('twitter_samples')
```

We can load the text fields of the positive and negative tweets by using the module's `strings()` method like this:

```
In [2]: # select the set of positive and negative tweets
all_positive_tweets = twitter_samples.strings('positive_tweets.json')
all_negative_tweets = twitter_samples.strings('negative_tweets.json')
```

Next, we'll print a report with the number of positive and negative tweets. It is also essential to know the data structure of the datasets

```
In [3]: print('Number of positive tweets: ', len(all_positive_tweets))
        print('Number of negative tweets: ', len(all_negative_tweets))

        print('\nThe type of all_positive_tweets is: ', type(all_positive_tweets))
        print('The type of a tweet entry is: ', type(all_negative_tweets[0]))
```

```
Number of positive tweets:  5000
```

```
Number of negative tweets:  5000
```

```
The type of all_positive_tweets is:  <class 'list'>
```

```
The type of a tweet entry is:  <class 'str'>
```

We can see that the data is stored in a list and as you might expect, individual tweets are stored as strings.

You can make a more visually appealing report by using Matplotlib's [pyplot](#) library. Let us see how to create a [pie chart](#) to show the same information as above. This simple snippet will serve you in future visualizations of this kind of data.

```
In [4]: # Declare a figure with a custom size
fig = plt.figure(figsize=(5, 5))

# labels for the two classes
labels = 'Positives', 'Negative'

# Sizes for each slide
sizes = [len(all_positive_tweets), len(all_negative_tweets)]

# Declare pie chart, where the slices will be ordered and plotted counter-clockwise:
plt.pie(sizes, labels=labels, autopct='%1.1f%%',
        shadow=True, startangle=90)

# Equal aspect ratio ensures that pie is drawn as a circle.
plt.axis('equal')

# Display the chart
plt.show()
```

1.3 Looking at raw texts

Before anything else, we can print a couple of tweets from the dataset to see how they look. Understanding the data is responsible for 80% of the success or failure in data science projects. We can use this time to observe aspects we'd like to consider when preprocessing our data.

Below, you will print one random positive and one random negative tweet. We have added a color mark at the beginning of the string to further distinguish the two. (Warning: This is taken from a public dataset of real tweets and a very small portion has explicit content.)

```
In [12]: # print positive in green
         print('\033[92m' + all_positive_tweets[random.randint(0,5000)])

         # print negative in red
         print('\033[91m' + all_negative_tweets[random.randint(0,5000)])
```

@MarkBreech Not sure it would be good thing 4 my bottom daring 2 say 2 Miss B but Im gonna be s

One observation you may have is the presence of [emojicons](#) and URLs in many of the tweets. This info will come in handy in the next steps.

1.4 Preprocess raw text for Sentiment analysis

Data preprocessing is one of the critical steps in any machine learning project. It includes cleaning and formatting the data before feeding into a machine learning algorithm. For NLP, the prepro-

cessing steps are comprised of the following tasks:

- Tokenizing the string
- Lowercasing
- Removing stop words and punctuation
- Stemming

The videos explained each of these steps and why they are important. Let's see how we can do these to a given tweet. We will choose just one and see how this is transformed by each pre-processing step.

```
In [13]: # Our selected sample. Complex enough to exemplify each step
        tweet = all_positive_tweets[2277]
        print(tweet)
```

My beautiful sunflowers on a sunny Friday morning off :) #sunflowers #favourites #happy #Friday

Let's import a few more libraries for this purpose.

```
In [14]: # download the stopwords from NLTK
        nltk.download('stopwords')
```

```
[nltk_data] Downloading package stopwords to /home/jovyan/nltk_data...
[nltk_data]   Unzipping corpora/stopwords.zip.
```

```
Out[14]: True
```

```
In [15]: import re                                # library for regular expression operation
        import string                             # for string operations

        from nltk.corpus import stopwords         # module for stop words that come with NLTK
        from nltk.stem import PorterStemmer       # module for stemming
        from nltk.tokenize import TweetTokenizer  # module for tokenizing strings
```

1.4.1 Remove hyperlinks, Twitter marks and styles

Since we have a Twitter dataset, we'd like to remove some substrings commonly used on the platform like the hashtag, retweet marks, and hyperlinks. We'll use the `re` library to perform regular expression operations on our tweet. We'll define our search pattern and use the `sub()` method to remove matches by substituting with an empty character (i.e. `' '`)

```
In [18]: print('\033[92m' + tweet)
        print('\033[94m')

        # remove old style retweet text "RT"
        tweet2 = re.sub(r'^RT[\s]+', '', tweet)

        # remove hyperlinks
```

```

tweet2 = re.sub(r'https?:\\\/.*[\\r\\n]*', '', tweet2)

# remove hashtags
# only removing the hash # sign from the word
tweet2 = re.sub(r'#', '', tweet2)

print(tweet2)

```

My beautiful sunflowers on a sunny Friday morning off :) #sunflowers #favourites #happy #Friday

1.4.2 Tokenize the string

To tokenize means to split the strings into individual words without blanks or tabs. In this same step, we will also convert each word in the string to lower case. The `tokenize` module from NLTK allows us to do these easily:

```

In [19]: print()
print('\033[92m' + tweet2)
print('\033[94m')

# instantiate tokenizer class
tokenizer = TweetTokenizer(preserve_case=False, strip_handles=True,
                           reduce_len=True)

# tokenize tweets
tweet_tokens = tokenizer.tokenize(tweet2)

print()
print('Tokenized string:')
print(tweet_tokens)

```

My beautiful sunflowers on a sunny Friday morning off :) sunflowers favourites happy Friday

1.4.3 Remove stop words and punctuations

The next step is to remove stop words and punctuation. Stop words are words that don't add significant meaning to the text. You'll see the list provided by NLTK when you run the cells below.

```

In [20]: #Import the english stop words list from NLTK
stopwords_english = stopwords.words('english')

print('Stop words\n')
print(stopwords_english)

print('\nPunctuation\n')
print(string.punctuation)

```

['i', 'me', 'my', 'myself', 'we', 'our', 'ours', 'ourselves', 'you', "you're", "you've", "you'll", "you can't"]

! " # \$ % & ' () * + , - . / : ; < = > ? @ [\] ^ _ ` { | } ~

For the punctuation, we saw earlier that certain groupings like ‘:)’ and ‘...’ should be retained when dealing with tweets because they are used to express emotions. In other contexts, like medical analysis, these should also be removed.

```
In [22]: print()
          print('\033[92m')
          print(tweet_tokens)
          print('\033[94m')

tweets_clean = []

for word in tweet_tokens: # Go through every word in your tokens list
    if (word not in stopwords_english and # remove stopwords
        word not in string.punctuation): # remove punctuation
        tweets_clean.append(word)

print('removed stop words and punctuation:')
print(tweets_clean)
```

Please note that the words **happy** and **sunny** in this list are correctly spelled.

All these words are stemmed from its common root **learn**. However, in some cases, the stemming process produces words that are not correct spellings of the root word. For example, **happi** and **sunni**. That's because it chooses the most common stem for related words. For example, we can look at the set of words that comprises the different forms of happy:

- 6

```
# call the imported function
tweets_stem = process_tweet(tweet); # Preprocess a given tweet

print('preprocessed tweet:')
print(tweets_stem) # Print the result
```

My beautiful sunflowers on a sunny Friday morning off :) #sunflowers #favourites #happy #Friday

That's it for this lab! You now know what is going on when you call the preprocessing helper function in this week's assignment. Hopefully, this exercise has also given you some insights on how to tweak this for other types of text datasets.
